This Event is brought to you for free and open access by the School of Nursing at Via Sapientiae. It has been accepted for inclusion in Grace Peterson Nursing Research Colloquium by an authorized administrator of Via Sapientiae. For more information, please contact digitalservices@depaul.edu.
Perceptions of Stress in Parents of Preterm Infants in the NICU

Master’s Entry into Nursing Practice 2017, DePaul University

Karina Ortiz

Background
Unexpected maternal or fetal complications occur in about 20% of women during pregnancy (Money & Gregory, 2012). Major complications often require infant admission to the neonatal intensive care unit (NICU), which can last several weeks to months depending on the severity of illness (Berry, Shah, Brouillette, & Hellmann, 2008). Though the NICU environment is there to promote longevity and sustainability to the lives of premature infants, it can be an unfamiliar and frightening environment to parents who are already in distress over their babies’ condition. The NICU environment involves invasive clinical procedures, frequent handling of their infant, and increased levels of auditory and visual stimulation. This can subject parents to psychological distress in addition to stress felt about their infant’s health and survival, disability risks, and disruption in their families and everyday life (Woodward et al., 2014). All of these factors can contribute to prolonged stress and coping in the parents of infants long after discharge from the NICU.

Methods
This study examined the impact of perceptions of stress in parents of preterm infants while in the NICU through an integrative literature review, which allows for a comprehensive evaluation of the strength of evidence concerning a phenomenon of concern. This lets the researchers critically appraise the strength and quality of each study, the implications of the knowledge, and identify gaps of knowledge for the purpose of developing new studies (Groene, Burns, & Gray, 2013). An integrative literature review is also useful in healthcare as the synthesis of qualitative and quantitative studies presents the opportunity in making informed decisions relating to the particular topic or phenomenon (Whitehouse & Kraft, 2005).

Purpose
The purpose of this literature review is to focus on parental perceptions of stress of premature infants as well as the negative effects on the psychological well-being of the parents.

Findings
Perceptions of stress:
• Environmental factors. A major source of stress includes the NICU environment, specifically the beeps coming from monitors, bright lights, and chemical odors (Turan, Başbakakkal, & Özbek, 2008).
• Infant’s appearance and behavior. High stress levels were also experienced for their infant’s appearance and behavior with many mothers reporting distress at how fragile or weak their infant looked (Turan, 2008).
• Alteration of parental role. Loss of their expected or desired role as a parent stems from not being able to perform normal acts such as feeding, which could lead to feelings of helplessness and frustration (Turan & Gregory, 2012).
• Lack of staff support. 22% of mothers and 19% of fathers described receiving little to no support for their loss in parental role from the nurses, and felt that nurses did not include them in discussions where decisions were made (Tandberg et al., 2013).

Negative mental health outcomes:
• Nontraumatic symptoms. More than 50% of mothers who experienced the NICU are at risk for PTSD (Money & Gregory, 2012). The majority (66.6%) of preterm infant mothers report symptoms such as elevated arousal, avoidance, and re-experiencing (Money & Gregory, 2012). They also experienced emotional responses such as guilt, defensiveness, and loss of control. These symptoms stayed elevated in mothers after 14 months of preterm birth versus mothers who delivered at full-term (Kantrowitz-Gordon, Allman & Vandermause, 2016).

• Depression and anxiety. Mothers displayed depressive symptoms, in which 13% of fathers had increased depression scores two years after preterm birth (Kantrowitz-Gordon et al., 2016). A mother’s depression after NICU admission has been associated with a negative perception of her child’s social abilities (Kantrowitz-Gordon et al., 2016). Families of full-term babies are shown to have lower stress, anxiety, and better family functioning than those of preterm babies (Kantrowitz-Gordon et al., 2016).

Discussion
This literature review was able to find various sources about the perceptions of stress felt by parents due to their infant’s NICU stay. These stressors significantly impact the mental health of the parents during and after discharge. Examples of negative mental health outcomes include PTSD, anxiety, and depression. These stressors can be improved upon by various strategies and techniques applied by NICU nurses. Effective communication and support from nurses are seen as interventions that can alleviate the demands felt by parents. Other recommendations include behavioral interventions programs for parents to promote interaction between them and their infants. Identifying and implementing effective programs can be beneficial to parents in generating more successful outcomes while in the NICU.

Nursing Implications
Nurses can play a crucial part for parents facing stressful and challenging times in the NICU. Nurses are familiar faces to NICU parents and often observe the difficult obstacles that parents experience. There is a lack of scientific evidence on possible nursing interventions and education that can help parents better adapt to this new stressful situation and environment. Therefore, recognizing these perceptions of stress is the stepping stone to identifying methods that nurses can apply to lower stress levels in parents. NICU nurses should also report increased maternal feelings and easier socialization when they felt nurses were communicative and encouraging participation in their infant’s care (Cleveland, 2009). A recommendation of education programs for nurses to improve their empathetic communication skills and promote mutual decision-making in order to help parents regain a sense of control is widespread in the literature.

Conclusion
Parents have various stressful perceptions when in the NICU with their premature infant. NICU nurses can address these concerns and feelings with empathetic communication skills and being aware of the importance of incorporating the parents as much as possible in their infant’s care. By addressing these concerns and negative perceptions of the NICU environment, NICU nurses can provide an opportunity for parents to overcome these stressful demands and maintain healthy mental health outcomes during and after discharge.
