Abstract

The project was designed to be an education outreach to Mt. Edgecumbe high school. Through this project students gained many skills and real life lessons which are not always taught in the class room. The skills gained from this trip are endless because of the many problems that were ran into. The ground station had the most problems. Student’s learned that you won’t always have access to what you need all the time, the students should bring extra hardware like the Ethernet adapter and USB splitters even if you think you won’t need it. The students also learned that it is important to have a checklist for projects like this to make sure that you have everything that is needed, having the check list was critical in figuring out what was wrong with the ground station when wires on the ground station and one of the payloads were broken. The students were able to identify where to look based on what worked as the check list was gone through. The last lesson learned that will always is apply to is check if the bill is paid. Personal Reflection: This project has impacted me to be apart of the STEM field, I come from a family of engineers and it has always been a dream of mine to become an Alaska Native engineer too. This project has given me a taste of what it would be like to become an engineer and I plan on going to college to achieve that goal. At this point I do know that I want to go to go in or out of state to experience life outside of Alaska. If I were to go to college in state UAF would be my first choice because of the engineering program and loads of opportunities there. Going into the STEM field is very important to me because I have a great passion for math and science. Working in the STEM field would not feel like a job because it is simply doing what I love. This project has shown me the importance of being thorough with my work so I can avoid such problems. I will never forget the experience I gained with this project.

Eclipse Day and Launch

The team arrived at Corvallis the night before the eclipse and began setting up their ground station. The team quickly found out that parts of the ground station broke during travel. The servo wire connections was severed and it had to be repaired. The students also determined that they needed extra equipment for their communicator to connect to the Ethernet. The students borrowed a USB splitter from Oregon Tech and an Ethernet to USB port adapter from Portland State to get the ground station up and running. Once the ground station was connected, the GPS tracker was operational but it was not showing up on the ground station website. It was determined that the bill was not paid so that it was actually offline.

On the morning of the eclipse the iodine sodium re-activated and every thing was set up smoothly. At launch, as the balloon was let go the cut down string snapped, freeing the balloon from the payload. PSU came to the rescue with a 3000 gram balloon and hydrogen gas and we launched 10 minutes after the scheduled launch time. We were on a rooftop at the OSU campus monitoring our ground station for about an hour. Finally it had reached totality and it was the craziest sight seeing a sunset and the stars in the middle of the day. After the eclipse the ground station stopped getting updates on the balloon. It was later suspected that our tracker failed due to the battery dying. Once the tracker got working we were too excited that we forgot to turn it off to preserve the battery. The tracker was on about 4 ½ hours before launch and died midnight.

Payloads and Preparation

The payloads were built as part of Mt. Edgecumbe’s science and technology class. The class was broken up into 6 units and each unit divided into three parts: introduction, research, and application to balloon project. The different units consisted of the solar system and eclipses, engineering design process, robotics, electrical engineering, computer programming and GPS tracking. To expand on a specific unit, the electrical engineering unit was taught in the three stages. Students learned what electrical engineers do, circuit basics, and related equations. In the related equations part, the students designed simple circuits, calculated the theoretical current and voltages in the design. The circuits were then built and the theoretical calculations were compared to measured values. The unit concluded with the students built up the eclipse hardware and software.

To prepare for the eclipse the students developed a preparation guide to setup the ground station and payloads. This testing guide provided step by step instructions to set up, turn on and turn off each system. The first integration of the balloon and payload were tested in the Mt. Edicumbre gym. The students got to fill their first balloon and test the whole system working together.

Conclusion

This project has given me a taste of what it would be like to become an engineer and I plan on going to college to achieve that goal. At this point I do know that I want to go to go in or out of state to experience life outside of Alaska. If I were to go to college in state UAF would be my first choice because of the engineering program and loads of opportunities there. Going into the STEM field is very important to me because I have a great passion for math and science. Working in the STEM field would not feel like a job because it is simply doing what I love. This project has shown me the importance of being thorough with my work so I can avoid such problems. I will never forget the experience I gained with this project.

This project is funded in part by the Alaska Space Grant Program.
